THE STUDY OF PRINCIPAL POLARIZATIONS THROUGH AUTOMORPHISMS OF THE JACOBIAN

DAMI LEE AND CATHERINE RAY

1. Introduction

Motivation: Narasimhan-Nori conjecture works in char 0, but is hard to implement Lang in code. Nothing has been done since Lang as far as we know, and nothing is known in char p.

In this paper, we recall different ways to compute period matrices of the Jacobians of curves. We introduce new code for brute force calculating many principal polarizations on these Jacobians.

It is hard to compare two principal polarizations, so we compute the automorphism group of the Jacobian with respect to them, and if these automorphism groups are nonisomorphic, the principal polarizations are nonisomorphic as well. This allows us to compare and study the principal polarizations further.

This paper proves no theorems, but rather introduces the codification of brute forcing principal polarizations, and shows how this can be used to

Along the way we found some surprises. For example, the Jacobian of Schoen's I-WP Surface has at least 9 nonisomorphic principal polarizations.

NEED TO ADDRESS HOW THE PERIOD MATRICES NEED NOT BE EXACT – see heuristics of Jeroen.

We stick to char 0 in this paper. We give several ways to compute period matrices of the Jacobians of curves.

We took the method of computing exact period matricies of cyclically branched covers from low dimensional geometry lore/folk tales (weber wrote it down in quartics paper).

We also take as input period matrices obtained from other, more general surfaces, such as modular curve, which is not cyclic.

We introduced the algorithm for brute computing PP from period matrices (even though Jeroen wrote it, not sure how to write this) – which works even on noncyclic covers.

We took the algorithm for computing the automorphism groups which preserve these pp also from https://arxiv.org/pdf/1807.02605.pdf

2. Period Matrices

2.1. **Computing the Period Matrix on Cyclic Covers.** In this section, we use the flat structure of a surface to compute the period matrix. We will look at the simplest case where $n = 3$ and $d_1 = 1$. Then, since $\sum d_i = d$, a cone metric with cone angles $\frac{2\pi}{d}(d_1, d_2, d_3)$ is admissible. Y is topologically equivalent to a doubled triangle with angles $\frac{2\pi}{d}(d_1, d_2, d_3)$ so we construct X with d copies of Y, which yields a flat structure on X. Figure **??** shows the flat structure of Klein's quartic.

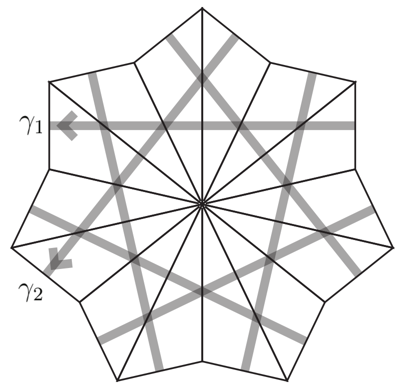

FIGURE 1. The flat fourteengon represents ω_1

The identification of edges are via parallel translations, which verifies that the cone metric is admissible. Identification of parallel edges yields closed cycles and the cyclicity gives away a homology basis with the following intersection matrix

$$\text{int} = \begin{pmatrix} 0 & 1 & 1 & 0 & 0 & -1 \\ -1 & 0 & 1 & 1 & 0 & 0 \\ -1 & -1 & 0 & 1 & 1 & 0 \\ 0 & -1 & -1 & 0 & 1 & 1 \\ 0 & 0 & -1 & -1 & 0 & 1 \\ 1 & 0 & 0 & -1 & -1 & 0 \end{pmatrix}.$$

Furthermore, we can produce flat structures that arise from ω_2 and ω_3 which are achieved from multipliers. The following period matrix is computed using the method from [**?**].

$$(\Pi) = (\int_\gamma \omega) = \begin{pmatrix} 1 & \zeta & \zeta^2 & \zeta^3 & \zeta^4 & \zeta^5 \\ 1 & \zeta^2 & \zeta^4 & \zeta^6 & \zeta^8 & \zeta^{10} \\ 1 & \zeta^4 & \zeta^8 & \zeta^{12} & \zeta^{16} & \zeta^{20} \end{pmatrix}$$

where ζ is the seventh root of unity.

2.2. **Other Curves (Not Cyclic Covers).** Summarize the known results (Jereon, also from blah's thesis)

3. Programmatically Computing the Automorphism Group of Plane Curves and Abelian Varieties over $\mathbb{C}$

Remark. This section is copied with from section 4 of Bruin-Sijsling-Zotine [**?**] with exposition and examples added for the readers' convenience.

Let us examine abelian varieties represented as analytic groups $X := V/\Lambda$ and $X' := V'/\Lambda'$. They need not be Jacobians.

Theorem (BL 1.2.1). *Let $X := V/\Lambda$ and $X' := V'/\Lambda'$ be abelian varieties. Under addition the set of homomorphisms* $\mathrm{Hom}(X, X')$ *forms an abelian group. There is an injective homomorphism of abelian groups:*

$$\rho : \mathrm{Hom}(X, X') \to \mathrm{Hom}(V, V')$$
$$f \mapsto F$$

The restriction to the lattice Λ is $\mathbb{Z}$-linear, thus we get an injective homomorphism:

$$\rho|_\Lambda : \mathrm{Hom}(X, X') \to \mathrm{Hom}_\mathbb{Z}(\Lambda, \Lambda')$$
$$f \mapsto F|_\Lambda$$

We will namely use the representation $\rho|_\Lambda$ and find the basis of our set of maps in terms of this representation.

We work in the category of varieties equipped with principal polarizations, which we discuss in section **??**. In this category, morphisms are morphisms of pairs. That is,

$$f : (X, c_1(\mathcal{L})) \to (Y, c_1(\mathcal{M}))$$

such that $f^*(Y, c_1(\mathcal{M})) = (X, c_1(\mathcal{L}))$ (for isomorphisms). We may represent polarizations as integral valued alternating forms.

Definition 1. Let a be a polarization of X. We call $\mathrm{Aut}(X, a)$ a **symplectic automorphism group** of X, as it respects the symplectic form a.

Let E_1 and E_2 be forms representing $c_1(\mathcal{L}_1)$ and $c_1(\mathcal{L}_2)$, respectively. Note that a map $\alpha : (X_1, c_1(\mathcal{L}_1)) \to (X_2, c_1(\mathcal{L}_2))$ such that

$$\alpha^*(c_1(\mathcal{L}_2)) = c_1(\mathcal{L}_1)$$

is equivalent to R in the image of $\rho|_\Lambda$ such that

$$R^t E_2 R = E_1$$

3.1. **Computing the Automorphism Group of Plane Curves.**

Remark. This section is on the algorithm used in `autplane.sage`.

In the case that our abelian variety is of the form $\mathrm{Jac}(C_i) =: J_i$, and we know the curve C_i, there is a special principal polarization E_i with respect to that curve C_i. This is programmatically found using Lemma 2.6 from [**?**].

Algorithm: Compute the set of isomorphisms between curves.
Input: Planar equations f_1, f_2 for curves C_1, C_2.
Output: The set of isomorphisms $C_1 \to C_2$, or the group $\mathrm{Aut}(C)$ if $C_1 = C_2$.

(1) Check if $g(C_1) = g(C_2)$; if not, return the empty set.
(2) Check if C_1 and C_2 are hyperelliptic; if so, use the methods in [**?**].
(3) Determine the period matrices P_1, P_2 of C_1, C_2 to the given precision.
(4) Determine a $\mathbb{Z}$-basis of $\mathrm{Hom}(J_1, J_2) \subset M_{2g\times 2g}(\mathbb{Z})$ represented by integral matrices $R \in M_{2g\times 2g}(\mathbb{Z})$. [Lemma 4.3 [**?**]]

(5) Using Fincke-Pohst[1], determine the finite set [from 5.1.9 BL]

$$S = \{R \in \mathrm{Hom}(J_1, J_2) \mid \mathrm{tr}((E_1^{-1} R^t E_2) R) = 2g\}$$

(6) Return the subset[2] of $R \in S$ which further satisfies $R^t E_2 R = E_1$. (These are the symplectic endomorphisms.)
(7) Look at the subset of R such that $\det(R) = \pm 1$. These are the symplectic automorphisms.
(8) If $J_1 = J_2$, find the group structure of this subset.

Note that if the curves C_1 and C_2 are non-hyperelliptic, by the precise Torelli theorem, we get $\mathrm{Hom}((J_1, E_1), (J_2, E_2)) \simeq \mathrm{Hom}(C_1, C_2) \sqcup \{\pm 1\}$ from this algorithm. So, we must remove the direct summand $\{\pm 1\}$.

Remark. Step 8 of the above algorithm was added by the second author to tame these unwieldy matrix groups, and is achieved as follows.

Algorithm: Compute the group structure of an underlying set of matrices.
Input: A set of matrices which are a group by multiplication.
Output: The group structure of the set.

(1) Check cardinality of the set. Call this N.
(2) Take first 15 elements of the set, use GAP to check if these generate a matrix group G of the correct order N. If not, it generates a group of order K, where $KM = N$. Take more elements of order dividing M until they generate a group of the correct order.
(3) Use `IdGroup(G)` in GAP.

3.2. Computing the Automorphism Group of Abelian Varieties.

Remark. This section is on the algorithm used in `autperio.sage`

Notation. Let $A := V/\Lambda$ be an abelian variety of dimension g. Let $e_1, ..., e_g$ be the chosen basis for V, and $\lambda_1, ..., \lambda_{2g}$ be a corresponding chosen basis for Λ. Let Π be the corresponding period matrix such that $A := \mathbb{C}^g/\Pi\mathbb{Z}^{2g}$.

Algorithm: Compute the group of isomorphisms between abelian varieties.
Input: Period matrices of abelian varieties J_1 and J_2, as Π_1 and Π_2 respectively.
Output: For each combination of principal polarizations (a_i, b_j), the set of isomorphisms between (J_1, a_i) and (J_2, b_j) (or the group, if they coincide).

(1) Check if $g_1 = g_2$; if not, return the empty set.
(2) Determine a $\mathbb{Z}$-basis of $\mathrm{Hom}(J_1, J_2) \subset M_{2g\times 2g}(\mathbb{Z})$ represented by integral matrices $R \in M_{2g\times 2g}(\mathbb{Z})$.
(3) Find many principal polarizations $\{a_i\}$ and $\{b_j\}$ for J_1 and J_2 respectively using `CullPB` (exposited in the next section).

---

[1]This is an algorithm for finding vectors of small norm. We use it here to solve for the finite set of solutions $R = \sum_{i=1}^{2g} \lambda_i B_i$, where B is the basis from step 4.

[2]The condition $R^t E_2 R = E_1$ (i.e., $E_1^{-1} R^t E_2 R = \mathrm{Id}$) implies that $\mathrm{tr}((E_1^{-1} R^t E_2) R) = 2g$. So we first solve for the latter to thin the results, then solve for the former from that set.

(4) Apply steps 5-8 of the previous section substituting each pair (a_i, b_j) for (E_1, E_2). For each pair, this will produce the set of isomorphisms between (J_1, a_i) and (J_2, b_j).
(5) If $(J_1, a_i) = (J_2, b_i)$, find the group structure of each set $\mathrm{Aut}(J_1, a_i)$ (using the algorithm in the previous section).

3.3. **Introduction to Polarizations: From Theory to Code.** The notion of a polarization of an abelian variety has many faces. If a complex torus has a polarization, it is an abelian variety.

Definition 2. A **polarization** of a complex torus X is an embedding $j : X \to \mathbb{P}^N$ for large enough N.

We can understand this embedding j as a map

$$p \mapsto [a_1(p) : \cdots : a_{N-1}(p)]$$

where a_i are a chosen generating set of global sections of a line bundle $\mathcal{L}$ on X.

Definition 3. A line bundle $\mathcal{L}$ is defined to be **very ample** on X if it defines a closed embedding into $\mathbb{P}^N$ for large enough N.

Definition 4. A line bundle is **ample** if a tensor power of the line bundle is very ample. Since the Chern class is additive, $c_1(\mathcal{L}^{\otimes k}) = kc_1(\mathcal{L})$, the ample bundle and its tensor power are equivalent datum.

Remark. In other words, $\mathcal{L}$ is defined to be ample if it (or a tensor power of it) specifies an embedding of X into projective space.

Definition 5. Line bundles $\mathcal{L}_1$ and $\mathcal{L}_2$ on X are **analytically equivalent** if there is a connected complex analytic space T, a line bundle $\mathcal{L}$ on $X \times T$, and points $t_1, t_2 \in T$ such that

$$\mathcal{L}|_{X\times\{t_i\}} \simeq \mathcal{L}_i$$

for $i = 1, 2$.

A line bundle $\mathcal{L}$ over X is specified up to analytic equivalence by its first Chern class $c_1(\mathcal{L}) \in H^2(X; \mathbb{Z})$. More precisely,

Theorem (2.5.3 BL)**.** *Let X be an abelian variety. For line bundles $\mathcal{L}_1$ and $\mathcal{L}_2$ over X, the following statements are equivalent:*
(1) $\mathcal{L}_1$ and $\mathcal{L}_2$ are analytically equivalent.
(2) $c_1(\mathcal{L}_1) = c_1(\mathcal{L}_2)$

Definition 6. The **first Chern class** of a line bundle $\mathcal{L}$ is the image of $\mathcal{L} \in \mathrm{Pic}(X) = H^1(\mathcal{O}_X^*)$ under the map c_1 on cohomology which arises as follows. Consider the exact sequence

$$0 \to \mathbb{Z} \to \mathcal{O}_X \to \mathcal{O}_X^* \to 0$$

and its long cohomology sequence:

$$\cdots \to H^1(\mathcal{O}_X^*) \xrightarrow{c_1} H^2(X, \mathbb{Z}) \to \cdots$$

We associate to every first Chern class an alternating form.

Theorem (BL 1.3.2 & 2.1.2)**.**

$$\psi : H^2(X;\mathbb{Z}) \simeq \mathrm{Alt}^2(\Lambda,\mathbb{Z})$$

Let S be the set of $c_1(\mathcal{L})$ where $\mathcal{L}$ ranges over all holomorphic line bundles on X. The image $\psi(S)$ is isomorphic to all Hermitian alternating forms.

Theorem (BL 2.1.6)**.** *Let $X := V/\Lambda$ be an abelian variety. For an alternating form $E : V \times V \to \mathbb{R}$, the following conditions are equivalent:*

(1) There is a holomorphic line bundle $\mathcal{L}$ on X such that $\psi(c_1(\mathcal{L})) = E$.
(2) $E(\Lambda,\Lambda) \subseteq \mathbb{Z}$, and

$$E(iv, iw) = E(v, w)$$

Remark. Note that from each element $\mathrm{Alt}^2(\Lambda,\mathbb{Z})$ we obtain via $\mathbb{R}$-linear extension an alternating form $\mathrm{Alt}^2(V,\mathbb{R})$ (as in rational versus analytic representation, see [BL 1.2.1]). We also have an isomorphism between real valued forms satisfying 2.1.6(2) and Hermitian forms.

It is important to emphasize that not all forms satisfying 2.1.6(2) correspond to Chern classes of ample line bundles. Ampleness is stronger than holomorphicity, hence we need a stronger condition.

Definition 7. A line bundle $\mathcal{L}$ on X is called **positive** if $c_1(\mathcal{L})$ is represented by a positive-definite Hermitian form.

Theorem. *Let X be a smooth complex projective variety. A line bundle $\mathcal{L}$ on X is ample if and only if it is positive.*

This is how we ask the computer to find polarizations of an abelian variety X, which are steps 1 and 2 of the following section.

However, there may be infinitely many polarizations. We are interested in a particular kind of polarization.

Definition 8. A polarization $c_1(\mathcal{L})$ of X is called **principal** if $\mathcal{L}$ has only one section up to constants, i.e. $\dim H^0(X,\mathcal{L}) = 1$.

As a motivational theorem:

Theorem (BL 4.1.2)**.** *Every polarization is induced by a principal polarization via an isogeny.*

By Narasimhan-Nori [**?**], there are only finitely many principal polarizations on a variety X, which is irreducible and smooth. And as a corollary, only finitely many curves may have the same Jacobian since each non-isomorphic curve gives a non-isomorphic principal polarization on its Jacobian.

3.4. **Finding Principal Polarizations.** We begin with a representation of our abelian variety as $A := \mathbb{C}^g/\Pi\mathbb{Z}^{2g}$.

Then Λ is the associated lattice spanned by the columns of Π. Thus, we have a distinguished basis for the homology of A, corresponding to the columns of Π.

Algorithm: Compute many principal polarizations on a given abelian variety A.

Input: An abelian variety $A := \mathbb{C}^g/\Pi\mathbb{Z}^{2g}$, where Λ is the associated lattice to the period matrix Π.

Output: Many principal polarizations on A.

(1) The magma function `FindPolarizationBasis` determines all integral alternating pairings E on the homology, i.e., $E \in \mathrm{Alt}^2(\mathbb{C}^g, \mathbb{Z})$, for whose real extension we have:

$$E(iv, iw) = E(v, w)$$

This is a basis of alternating forms $\{E_i\}$.

(2) Check that E is positive-definite.

(3) `CullPB.m` tries some small combinations and sees if E_i actually gives a pairing with determinant 1 indicating that E_i is a principal polarization. If so, it returns E_i. This gives us a set $\{E_k\}$ of integral pairings on the homology.

(4) For each i, we rewrite these pairings in a symplectic basis. That is, we find a basis of Λ in which

$$E_i = \begin{pmatrix} 0 & D \\ -D & 0 \end{pmatrix}$$

where $D = \mathrm{diag}(d_1, ..., d_g)$ which we may do by the elementary divisor theorem (section 3.1, [**?**]).

Remark. This does nothing but modify the (homology) basis of Λ. Multiplying Π on the right with this integral matrix, we get a new period matrix Q whose columns span exactly the same lattice but for which the standard symplectic pairing E is actually the Chern class of a line bundle. This is often called the Frobenius form of the period matrix Π.

Definition 9. We say two principal polarizations p_1 and p_2 on A are **auto-equivalent** if and only if $\mathrm{Aut}(A, p_1) \simeq \mathrm{Aut}(A, p_2)$.

This program produces many auto-equivalent principal polarizations. When this equivalent relation is taken, it greatly reduces the number of principal polarizations. Note that auto-equivalence is a weaker notion of equivalence than analytic equivalence, as discussed in section **??**.

If the abelian variety is indeed a Jacobian, this method will in practice return at least enough polarizations to find the canonical principal polarization. It is an unsolved problem to find all possible principal polarizations associated to a given abelian variety, called “explicit Narasimhan-Nori”.

3.5. **Abelian Varieties with Several Principal Polarizations.** An unexpected result of this paper was finding multiple non-autoequivalent principal polarizations on many different Jacobians using a method not found in the literature. Before we state our result we summarize what is known about abelian varieties with several principal polarizations.

Definition 10. An abelian variety is **simple** if it is not isogenous to a product of abelian varieties of lower dimension.

Some previous work on finding multiple principal polarizations on abelian varieties has been done by finding two non-isomorphic curves with the same (unpolarized) Jacobian. Therefore, their associated canonical polarizations must be different by the Torelli theorem. Otherwise, the curves would be isomorphic. There are papers which discuss the non-simple case at genus two [**?**] and three [Brock, *Superspecial curves of genera two and three*], though the authors was unable to find a copy of the latter.

Remark. There is only a canonical principal polarization on A if a curve C is specified so that $A = \mathrm{Jac}(C)$. In other words, knowing that A is in the image of the functor Jac is not enough.

Another technique is used in [**?**] and [**?**] by E. Howe which gives examples of genus two curves that are non-isomorphic but give the same (simple) Jacobian. He does this in characteristic p by playing with isogeny classes of abelian varieties which correspond to special Weil numbers. In [**?**] Theorem 1.5, Lange establishes that the order of $\mathrm{Aut}(A)$ with certain restriction conditions and equivalence relations is equal to the number of principal polarizations on A up to isomorphism, $\pi(A)$. This bijection between sets is induced by a principal polarization, so one must know that one exists to implement this theorem. One could compute the size of this specially carved out version of $\mathrm{Aut}(A)$ by hand using Lange's theorem. However, we compute directly the principal polarizations on A with the aid of a computer.

We use an entirely different technique, exposited in Section **??**, which treats both simple and non-simple cases. This technique, for example, gives us 9 not auto-equivalent principal polarizations on the Jacobian of Schoen's I-WP Surface. This is a very interesting result, especially since the variety Jac(I-WP) itself factors into a product of 4 elliptic curves[3], so the remaining principal polarizations must come from interesting new cycles in the product of these elliptic curves. Other such results from this technique are shown in Table **??**.

Remark. Since every abelian variety is isogenous to a product of simple abelian varieties

$$A \simeq A_1 \times ... \times A_k$$

it is reasonable to ask how the numbers of principal polarizations on A_i are related to that of A.

Let's quickly establish some vocabulary to discuss this intuitively. Recall that we may also define a principal polarization on A as an isogeny which is also an isomorphism between $A \to A^\vee$, where $A^\vee$ denotes the dual variety. Let A and B be arbitrary abelian varieties. Note that $\mathrm{Corr}(A, B) \simeq \mathrm{Hom}(B, A^\vee)$, where we take a correspondence from A to B to be a line bundle $\mathcal{L}$ over the product $A \times B$ which is trivial when restricted to A or B.

We are interested in $\mathrm{Aut}(A, A^\vee)$, which is isomorphic to $\mathrm{Corr}(A, A)^\times$ but the problem of comparision arises immediately and obviously without having to pass to isomorphisms.

We wish to compare

[3]This is because $\mathrm{End}(\mathrm{Jac(I\text{-}WP)}) \simeq M_4(K)$, where K is imaginary quadratic. Thus, Jac(I-WP) is the product of elliptic curves with CM by K.

$$\mathrm{Corr}\left(\prod_{j=1}^{k} A_j, \prod_{i=1}^{k} A_i\right) \qquad \text{and} \qquad \prod_{i,j} \mathrm{Corr}(A_j, A_i)$$

Let C and D be abelian varieties. Given a line bundle on C and on D, we get a line bundle on $C \times D$, but not vice-versa. Intuitively, the product $C \times D$ may have many more interesting cycles than the product of the cycles of C and D, and may not necessarily restrict to a line bundle on C or D. Therefore, in general the number of principal polarizations of A is at least the product of the principal polarizations of the simple components A_i, that is,

$$\pi(A_1 \times ... \times A_k) \geqslant \prod_{i=1}^{k} \pi(A_i)$$

as observed. We saw that Jac(I-WP) is isogenous to a product of 4 elliptic curves. Since these curves are all isomorphic, we only get one principal polarization from this decomposition, but we found at least 9 principal polarizations on their product.

TABLE 1. Automorphism Groups wrt each of the Principal Polarizations

Curve C	Genus	# Principal Polarizations	$\mathrm{Aut}(\mathrm{Jac}(C), a_i)$	$\lvert\mathrm{Aut}(\mathrm{Jac}, a_i)\rvert$	GAPID
Klein	3	2	$S_4 \times C_2$	48	[48, 48]
			$GL_3(F_2) \times C_2$	336	[336, 209]

			$C_6 \times (S_3 \times ((C_6 \times C_2) : C_2))$	864	[864, 4523]
$X_0(63)$	5	2	$C_2^{\ 5}$	32	[32,51]
			$C_2^{\ 2} \times S_4$	96	[96, 226]

4. CLOSING REMARKS

We speak here of polarizations up to auto-equivalence and ask natural questions on Jacobians with multiple principle polarizations, answering all but one of the questions using methods developed in our paper.

We fix some notation. Let θ_C be the canonical principal polarization of $\mathrm{Jac}(C)$ with respect to C. We call $\mathrm{Aut}(A, a_i)$ a symplectic automorphism group of A, as the automorphisms respect the principal polarization a_i, which is a symplectic form on A.

Question. $\mathrm{Aut}(\mathrm{Jac}(C), \theta_C)$ *will have the highest order of all symplectic automorphism groups of* $\mathrm{Jac}(C)$.

This is proven false by example $12(1,5,6)$, where $\lvert \mathrm{Aut}(\mathrm{Jac}(12(1,5,6)), \phi_{12(1,5,6)})\rvert = 24$, but $\lvert \mathrm{Aut}(\mathrm{Jac}(12(1,5,6)), a_i)\rvert = 32$ is achieved. It is more dramatically proven false by Schoen's I-WP Surface, where $\lvert \mathrm{Aut}(\mathrm{Jac}(\text{I-WP}), \phi_{\text{I-WP}})\rvert = 288$, but $\lvert \mathrm{Aut}(\mathrm{Jac}(\text{I-WP}), a_i)\rvert$ achieves 576 and 864.

Question. *Principal polarizations p_1 and p_2 are auto-equivalent if and only if they are analytically equivalent. In other words,*

$$\mathrm{Aut}(X, p_1) \simeq \mathrm{Aut}(X, p_2) \Leftrightarrow p_1 = p_2$$

The direction ($\Leftarrow$) is clear because $\mathcal{L}$ and $\mathcal{M}$ are analytically equivalent if and only if $c_1(\mathcal{L}) = c_1(\mathcal{M})$ by [BL 2.5.3]. The other direction is false. This is proven false by the following two *non-isomorphic* curves with the same (unpolarized) Jacobian from Theorem 1 [**?**]:

$$X : 3y^2 = (2x^2 - 2)(16x^4 + 28x^2 + 1)$$

$$X' : -y^2 = (2x^2 + 2)(16x^4 + 12x^2 + 1)$$

which both have $\mathrm{Aut}(\mathrm{Jac}(X), \theta_X) \simeq C_2 \times C_2 \simeq \mathrm{Aut}(\mathrm{Jac}(X'), \theta_{X'})$.

Question. *If* $\mathrm{Jac}(C) \simeq \mathrm{Jac}(C')$ *as complex varieties, then*

$$\mathrm{Aut}(\mathrm{Jac}(C), \theta_C) \simeq \mathrm{Aut}(\mathrm{Jac}(C'), \theta_{C'})$$

We checked this question on the family of hyperelliptic cases of genus 2 from [**?**] Theorem 1, where it is true. However, there is no reason to expect this to be true in general. Yet, we cannot disprove it easily.
